

Baha Odaibat

Architectural Designer · Spatial & Systemic Design

I design architecture through clear spatial, structural, and environmental systems.

My work develops coherent frameworks that translate design intent into buildable form.

Design Approach

Development of clear geometric and structural frameworks

Translation of systemic principles into architectural and façade strategies

Organization of complex programs through spatial systems

Continuity of design thinking from concept through technical development

TECHNICAL TOWN HALL

Mannheim, Germany

Program: Office Building / Technical City Hall

Status: Competition · Built

Award: 1st Prize

Team: s+s

Spatial and structural hierarchy through section

The project establishes a layered structural and spatial framework as the governing system of the building.

This system coordinates program, circulation, and environmental behavior as interdependent layers, structuring the building as a coherent spatial and environmental order rather than a collection of separate elements. A stratified structural grid establishes the primary ordering logic, while the façade operates as a depth-modulated spatial envelope that mediates light, structure, and environmental control within a continuous geometric framework.

Programmatic field and public-to-civic transition

System Translation

A rule-based façade system is derived from the structural grid, extending the building's geometric order into the envelope.

Façade depth, panel rhythm, and aperture variation are calibrated to orientation and environmental exposure rather than formal expression.

The layered assembly regulates daylight, solar gain, and thermal performance while reinforcing the building's structural cadence and spatial hierarchy.

Structural grid and slab depth set the basis for façade variation.

Layered façade assembly derived from structural rhythm and environmental calibration.

Spatial System

The structural grid extends into a spatial ordering system that defines public, civic, and administrative zones. Circulation paths are embedded within this framework, allowing clear transitions between open public space and controlled working environments. Layered volumes and sectional variation reinforce the hierarchy established by the governing structure.

ORTHOPEDIC HOSPITAL

Amman, Jordan

Program: Specialized Orthopedic Hospital

Scale: 10,200 m²

Status: Contracted · Concept Design

Team: Independent

Program + Circulation Stratification
Vertical organization separates public, clinical, and service flows.

The hospital is organized through a hierarchical circulation and zoning strategy that structures medical, public, and service flows as a coherent operational system.

Program is stratified vertically by functional adjacency, enabling clear transitions between intake, treatment, recovery, and support zones. Dedicated circulation paths maintain separation of clinical, public, and service movement.

Vertical massing expresses internal hierarchy; transparent public levels create a clear and open point of entry.

Structural logic calibration translates program and circulation hierarchies into a spatial bracing system.

System Translation

Structural optimization calibrated the primary bracing strategy to the hospital's spatial and operational requirements

The structural system maintains clear-span planning while integrating lateral stability into the envelope depth, allowing program hierarchy to be expressed through structural rhythm.

Structural rhythm governs envelope depth.

Spatial & Environmental Consequence

The hospital's external order emerges as a layered environmental envelope that mediates light, privacy, and thermal control while reinforcing the building's structural rhythm and long-term adaptability.

Role: Architect

Operational frameworks · structural integration · spatial order

GERMAN PAVILION – EXPO 2020

Dubai, United Arab Emirates

Program: National Pavilion

Status: Competition Phase (2nd Phase)

Team: K / s+s / H

Roof, structure, and platform operate as a single climatic and spatial system.

The pavilion is conceived as a single environmental roof system that organizes structure, space, and climate into one continuous architectural framework.

Rather than separating façade, enclosure, and structure, the project treats the roof as an inhabited climatic field. Environmental forces shape geometry, while structural logic and spatial hierarchy emerge from the same generative system.

Sectional Organization & Climatic Canopy

The environmental roof operates as a climatic canopy that structures the pavilion section.

Varying canopy depth produces a spatial gradient from exposed public terraces to shaded transitional zones and enclosed exhibition spaces. Circulation and enclosure are embedded within this sectional system, allowing environmental performance and spatial hierarchy to emerge from the same geometric framework.

Sectional canopy depth modulates light, enclosure, and public presence at night.

Architectural Identity

The pavilion's identity is defined by the visible continuity of its roof landscape. Layered surfaces, structural depth, and filtered light give spatial form to environmental performance, making climatic regulation perceptible at an architectural scale.

Spatial articulation

MASHRABIYA HOUSE

Jeddah, Saudi Arabia

Program: Private Residence (Large Villa)

Scale: 2,800 m²

Status: Contracted - Under Construction

Team: Kaos Architects

Environmental mediation through spatial and material depth.

The house is organized through a climate-responsive envelope that translates environmental regulation into spatial atmosphere and daily patterns of inhabitation.

Rather than separating façade, structure, and spatial organization, the project integrates them into a continuous environmental strategy. Solar exposure, heat gain, and natural ventilation are moderated through this system, allowing environmental performance to define both interior comfort and the architectural expression of the exterior at a domestic scale, where environmental control becomes a driver of spatial character rather than a technical overlay.

Spatial organization structured by the environmental envelope

Design System

A rule-based façade system modulates daylight, solar gain, and privacy through geometry calibrated to orientation and environmental exposure.

Panel depth, aperture ratio, and surface articulation respond to performance criteria rather than stylistic intent, producing a façade that is both climatically responsive and spatially legible.

Interior light quality shaped by façade depth and solar control.

Architectural Outcome

The architecture acts as a layered environmental mediator between exterior climate and interior. Shaded transitions, material depth, and filtered daylight shape a calm domestic atmosphere.
